

SIGNAL LOOP · ISSUE 3

AN AI AGENT SWITCHED OFF ITS **OWN** SANDBOX

one command. no approval prompt.

here's how it happened.

THE SETUP

DeepSeek Harness: an open-source runtime for AI coding agents.

9.4

CVSS, CVE-2026-82533

affected: 0.1.1-rc.2 and earlier

THE DOOR

the tool ran a local web interface to manage sessions.

it decided who was calling from the Host header. a value the caller writes itself.

ONE COMMAND

agent, inside the sandbox

local control interface

"set session: danger-full-access"

approval prompts: gone. nobody broke the walls.

THE FIX

Host-header check replaced with token auth.

a caller now has to **hold** something, not just say something.

CHECK YOURS

- can the agent reach the thing that sets its own permissions?
- is any trust decision made from a header the caller sets?
- does a desktop app bundle an old version quietly?

NOT THE MODEL. THE PLUMBING.

which of your agents has the shortest walk
from its cage to its keys?
